NT-Cryptography MAT4930 *7554* | **Home-C** | Prof. JLF King *Touch*: 4Aug2016

Due **BoC, Monday, 07Apr2014**. Please *fill-in* every *blank* on this sheet.

C1: *Show no work. Please write* **DNE** *in a blank if the described object does not exist or if the indicated operation cannot be performed.*

a Posints $K=$ ____, $N=$ ____, $\alpha=$ ____, $\beta=$ ____, are st. $\alpha \equiv_K \beta$, yet $N^\alpha=$ ____ is **not** $\equiv_K$ to $N^\beta=$ ____.

b Using dictionary 0: ε, 1: "1", 2: "0", compute EnZiv(11110110)= ____, in $\langle 7\rangle 1\langle 34\rangle 0\ldots$ notation. In bits, EnZiv(11110110) is ____.

OYOP: *Your 2 essay(s) must be* TYPESET*, and Double or Triple spaced. Use the Print/Revise cycle to produce good, well thought out, essays. Start each essay on a* **new** *sheet of paper.*

Do **not** *restate the problem; just solve it.*

C2: Let $\vec{1} := 1111\ldots$, the half-∞ constant-1 bit-string. Using our Ziv-algorithm, with dictionary that [initially] only has the nullword, we start parsing $\vec{1}$.

Let $P(k)$ be the largest-number of bits we've parsed, having used-up at most k many bits from $\vec{1}$. I.e, we Ziv-parse, and we eventually parse a new word [which we enter into our dictionary], having read exactly $P(k)$ many bits, in total, where $P(k) \leqslant k$. As we scan for the next new word, we run past the k^{th}-bit in $\vec{1}$.

i Give an approximate formula for $N(k)$, the number of words you've parsed, having read the first $P(k)$ many bits.

ii Let $Z(k)$ be the length of the Ziv-compressed bit-string that encodes the first $P(k)$ many bits in the source-string. When k is large, give a pretty good estimate for $Z(k)$; a "closed formula", neither having a $\sum$ summation operator, nor a $\prod$ product operator.

What are approximate values for $N(500,000)$, and for $Z(500,000)$?

Compute $\lim_{k\to\infty} \frac{Z(k)}{k}$.

C3: Consider posreals $p+q=1$. Your coin outputs bit 0 with prob.=p, and bit 1 with prob.=q. Flipping the coin K times, the WLLN [Weak Law of Large Numbers] says, when K is "large", that a typical sequence has about pK many 0s, and has about qK many 1s.

α Let $f(K)$ denote the number of such length-K bit-sequences. Estimate $f(K)$ using a binomial coefficient.

Now use Stirling's formula to get an "algebraic" estimate for $f(K)$ that just uses multiplication, division, and powers; it does *not* use factorials.

β Define a fnc g by: $\boxed{2^{[K\cdot g(K)]} = f(K)}$. Using your "algebraic" formula for f, derive a formula estimating $g(K)$.

Assuming that all of your estimates could be proved rigorously, compute $\lim_{K\to\infty} g(K)$. What familiar formula is this limit?

γ Using these ideas, do something extra. Impress me. [Hopefully, not with a brick...]

End of Home-C

C1:	___ ___	40pts
C2:	___ ___	85pts
C3:	___ ___	95pts
Total:	___ ___ ___	220pts
